
Appendix E

Methodology for Estimating Catchment Populations of Renal Centres in England for Dialysis Patients

This is primarily the work of Andrew Judge. Others who assisted include (listed alphabetically): David Ansell, Yoav Ben-Shlomo, Daniel Ford, Paul Roderick and Charlie Tomson.

Introduction

Providing accurate centre-level incidence and prevalence rates for patients receiving renal replacement therapy (RRT) in the UK has been limited in the past by the difficulty in estimating the catchment population from which the RRT population was derived. One reason for this is that the geographical boundaries separating renal centres are relatively arbitrary and dependent upon a number of factors including referral practice, patient choice and patient movement. Previously, incidence and prevalence rates have been calculated at Local Authority/Primary Care Trust/Health Board level where denominator data were available, but not at renal centre level.

Previous UK Renal Registry (UKRR) Annual Reports have suggested an estimate of the size of the catchment populations. These were extrapolated figures originally derived from data in the 1992 National Renal Survey undertaken by Paul Roderick.

The purpose of this appendix is to present an estimate of the dialysis catchment population for all renal centres in England. The document also contains a methodological description and discussion of the limitations of

this estimate. These catchment population estimates have been used in this report (chapter 1: UK RRT Incidence in 2009: national and centre-specific analyses) to calculate RRT incidence rates by renal centre, rather than only by Primary Care Trust/HB.

Methods

The UKRR database of the UK prevalent dialysis population on 31st December 2007 was used to estimate the size of each renal centre's catchment population. This used the postal code address and dialysis centre for each individual UK dialysis patient.

An area was drawn around the geographical location of each dialysis patient, producing an overlapping polygonal area. The shape and size of this area was based upon the location of other dialysis patients surrounding them. Using these areas for individual patients, the total catchment area for each renal centre was merged and the Office for National Statistics (ONS) census-area statistics (CAS) wards overlaid upon the renal centre catchment area. Each CAS-ward was then assigned to the corresponding renal centre. If more than one renal centre catchment area corresponded to a CAS-ward, then only a percentage of the ward was assigned to each centre, proportionate to the area covered.

The ONS publishes the number of people living in each ward, based upon the April 2001 Census. This information is available on the ONS website. This

information was used to calculate the number of people living in the census ward allocated to each renal centre. If only a proportion of a ward was allocated to a centre, then the same proportion of the population was attributed to that centre's denominator.

The ONS annually estimates the increase in the UK population at national and Local Authority level. When the work detailed here was prepared the latest update available was to June 2008. The ONS also updates the population estimates at CAS-ward level. The latest update available at CAS-ward level was to June 2007. This information was not available on the ONS website but was provided by direct communication and permission granted for use in this analysis. It was necessary to use the ONS data at the CAS-ward level, therefore the June 2007 data were used for the latest UKRR analysis.

The allocation of catchment ward to renal centre was only undertaken for England and therefore estimated catchment populations for renal centres in Scotland, Wales and Northern Ireland have not been calculated.

This allocation exercise was performed before Colchester became a separate renal centre.

Results

The estimated dialysis catchment populations for renal centres in England are shown in table E.1. The table shows both calculations: firstly from the ONS Census from April 2001 and secondly from the updated ONS estimates of CAS-ward populations at June 2007.

Discussion

These results show the updated estimates for the size of the catchment areas for each of the renal centres in England. This is the first time that the UK Renal Registry

Table E.1. Estimated dialysis catchment populations of English renal centres based upon 2001 and mid-2007 ONS CAS-ward population estimates (rounded to nearest 1,000)

Centre	2001 estimate	Mid-2007 estimate	Centre	2001 estimate	Mid-2007 estimate

* some reduction required after the opening of Colchester renal centre

** population may be too low as centre has expanded

has been able to accurately estimate the catchment population for each English centre.

There are some limitations to these results. The first is that the ward allocated to each renal centre was based upon dialysis patients only. Therefore it is possible that non-dialysis patients may come from a different catchment population. This is more likely where a renal centre provides specialist services and especially likely for patients undergoing renal transplantation. The catchment population for renal transplant patients will depend largely upon the distribution of workload between the referral centre and the transplanting centre for pre-transplant work-up, donor nephrectomy work-up and post-transplant care (including if and when care is returned to the referring centre).

These estimates were performed before Colchester became a separate renal centre. Therefore it is likely that the catchment populations of the neighbouring

renal centres: Chelmsford, Ipswich and Cambridge, are somewhat too high. It is thought that the catchment population of Colchester may be in the region of 200,000 people.

Despite these limitations, this is the most valid methodology to date to estimate the size of the catchment populations for renal centres in England. The results of this analysis allow the UKRR to calculate estimates of the incidence and prevalence rates of renal replacement therapy at renal centre level, rather than only at PCT/HB level.

These results also provide other opportunities for study of the catchment populations. The ONS provides data on gender, age and ethnicity of the population at ward level. It should be possible to use this information to consider centre differences in the demographics of patients commencing or receiving RRT with adjustment for the catchment population characteristics.
